Exercise: Arithmetic and Variable... Draft saved

File Edit View Run Add-ons Help

+ X D C P R A

This notebook is an exercise in the [Intro to Programming](#) course. You can reference the tutorial at [this link](#).

This exercise will get you started with running your own code.

## Set up the notebook

To begin, run the code in the next cell.

- Begin by clicking inside the code cell.
- Click on the triangle (in the shape of a "Play button") that appears to the left of the code cell.
- If your code was run successfully, you will see `Setup Complete` as output below the cell.

Instead of clicking on the triangle, you can also run code by pressing Shift + Enter on your keyboard. Try this now! Nothing bad will happen if you run the code more than once.

```
[1]: # Set up the exercise
from learntools.core import binder
binder.bind(globals())
from learntools.intro_to_programming.ex1 import *
print('Setup complete.')
```

Setup complete.

The code above sets up the notebook so that it can check your answers in this exercise. You should never modify this code. (Otherwise, the notebook won't be able to verify that you have successfully completed the exercise.)

After finishing all of the questions below, you'll see the exercise marked as complete on the [course page](#). Once you complete all of the lessons, you'll get a course completion certificate!

## Question 1

Next, you will run some code from the tutorial, so you can see how it works for yourself. Run the next code cell without changes.

```
[2]: print("Hello, world!")
# DO NOT REMOVE: Mark this question as completed
q1.check()
```

Hello, world!

If you see "Hello, world!" above, You have successfully printed a message, and you're ready to move on to the next question.

You just ran code to print `Hello world!`, which you should see in the output above.

The second line of code (`q1.check()`) checks your answer. You should never modify this checking code; if you remove it, you won't get credit for completing the problem.

## Question 2

Now, you will print another message of your choosing. To do this, change `print("Your message here!")` to use a different message. For instance, you might like to change it to something like:

- `print("Good morning!")`
- `print("I am learning how to code :D")`

Or, you might like to see what happens if you write something like `print("3+4")`. Does it return 7, or does it just think of "`3+4`" as just another message?

Make sure that your message is enclosed in quotation marks (" "), and the message itself does not use quotation marks. For instance, this will throw an error: `print("She said "great job" and gave me a high-five!")` because the message contains quotation marks. If you decide to take the Python course after completing this course, you will learn more about how to avoid this error in [Lesson 6](#).

Feel free to try out multiple messages!

```
[3]: # TODO: Change the message
print("I can do this!")

# DO NOT REMOVE: Mark this question as completed
q2.check()
```

The screenshot shows a Kaggle Notebook interface. The title bar reads "Exercise: Arithmetic and Variables" and "kaggle.com/code/vemaiensi/exercise-arithmetic-and-variables/edit". The notebook content includes a code cell with Python code and a message about commenting. The sidebar on the right contains sections for "Notebook", "Data", "Input", "Models", and "Code Help".

**Exercise: Arithmetic and Variables...** Draft saved

File Edit View Run Add-ons Help

message contains quotation marks. If you decide to take the Python course after completing this course, you will learn more about how to avoid this error in [Lesson 6](#).

Feel free to try out multiple messages!

```
[3]: # TODO: Change the message
print("I can do this!")

# DO NOT REMOVE: Mark this question as completed
q2.check()
```

I can do this!

Once you have printed your own message, you're ready to move on to the next question.

### Question 3

As you learned in the tutorial, a comment in Python has a pound sign (#) in front of it, which tells Python to ignore the text after it.

Putting a pound sign in front of a line of code will make Python ignore that code. For instance, this line would be ignored by Python, and nothing would appear in the output:

```
#print(1+2)
```

Removing the pound sign will make it so that you can run the code again. When we remove the pound sign in front of a line of code, we call this **uncommenting**.

In this problem, you will uncomment two lines in the code cell below and view the output:

- Remove the # in front of `q3_hint()`. To avoid errors, do NOT remove the # in front of `# Uncomment to view hint`.
- Next, remove the # in front of `q3.solution()`.

As in the previous questions, do not change the final line of code that marks your work as completed.

```
[4]: # Uncomment to get a hint
q3_hint()

# Uncomment to view solution
q3.solution()

# DO NOT REMOVE: Check your answer
q3.check()
```

**Hint:** If you're ever stuck on a question, it's a good idea to look at the hint before viewing the solution.

**Solution:** If you're still stuck on a question after viewing the hint and re-reading the tutorial, you can view the solution. You can also view the solution after you have successfully submitted your own answer, to check if the official solution is any different (there may be more than one right answer!).

Once you have printed the hint and the solution, you're ready to move on to the next question.

In the next question, and in most of the exercises in this course, you will have the option to uncomment to view hints and solutions. Once you feel comfortable with uncommenting, continue to the next question.

### Question 4

In the tutorial, you defined several variables to calculate the total number of seconds in a year. Run the next code cell to do the calculation here.

```
[5]: # Create variables
num_years = 4
days_per_year = 365
hours_per_day = 24
mins_per_hour = 60
secs_per_min = 60

# Calculate number of seconds in four years
total_secs = secs_per_min * mins_per_hour * hours_per_day * days_per_year * num_years
print(total_secs)
```

126144000

Arithmetic and Variables | Kaggle    Exercise: Arithmetic and Variables

kaggle.com/code/vemaiensi/exercise-arithmetic-and-variables/edit

Exercise: Arithmetic and Variables... Draft saved

File Edit View Run Add-ons Help

+ X D C P R

126144000

Use the next code cell to:

- Define a variable `births_per_min` and set it to 250. (There are on average 250 babies born each minute.)
- Define a variable `births_per_day` that contains the average number of babies born each day. (To set the value of this variable, you should use `births_per_min` and some of the variables from the previous code cell.)

Remember you can always get a hint if you need it!

```
[6]: # TODO: Set the value of the births_per_min variable
births_per_min = 250

# TODO: Set the value of the births_per_day variable
births_per_day = births_per_min * mins_per_hour * hours_per_day

# DO NOT REMOVE: Check your answer
q4.check()
```

Correct

```
[ ]: # Uncomment to get a hint
#q4.hint()

# Uncomment to view solution
#q4.solution()
```

## Question 5

(Questions marked with a 🌶 will be a little bit more challenging than the others! Remember you can always get a hint or view the solution.)

The [Titanic competition](#) is Kaggle's most famous data science competition. In this competition, participants are challenged to build a machine learning model that can predict whether or not passengers survived the Titanic shipwreck, based on information like age, sex, family size, and ticket number.

Run the next code cell without changes to load and preview the titanic data.

Don't worry about the details of the code for now - the end result is just that the all of the titanic data has been loaded in a variable named `titanic_data`. (In order to learn how to write this code yourself, you can take the [Python course](#) and then the [Pandas course](#).)

```
[7]: # Load the data from the titanic competition
import pandas as pd
titanic_data = pd.read_csv("../input/titanic/train.csv")

# Show the first five rows of the data
titanic_data.head()
```

	PassengerId	Survived	Pclass	Name	Sex	Age	SibSp	Parch	Ticket	Fare	Cabin	Embarked
0	1	0	3	Braund, Mr. Owen Harris	male	22.0	1	0	A/5 21171	7.2500	Nan	S
1	2	1	1	Cumings, Mrs. John Bradley (Florence Brigitte Th...	female	38.0	1	0	PC 17599	71.2833	C85	C
2	3	1	3	Heikkinen, Miss. Laina	female	26.0	0	0	STON/O2. 3101282	7.9250	Nan	S
3	4	1	1	Futrelle, Mrs. Jacques Heath (Lily May Peel)	female	35.0	1	0	113803	53.1000	C123	S
4	5	0	3	Allen, Mr. William Henry	male	35.0	0	0	373450	8.0500	Nan	S

The data has a different row for each passenger.

The next code cell defines and prints the values of three variables:

- `total` = total number of passengers who boarded the ship
- `survived` = number of passengers who survived the shipwreck
- `minors` = number of passengers under 18 years of age

Run the code cell without changes. (Don't worry about the details of how these variables are calculated for now. You can learn more about how to calculate these values in the [Pandas course](#).)

Exercise: Arithmetic and Variables... Draft saved

File Edit View Run Add-ons Help

+ ✎ 📁 📂 ⏪ ⏩ Run All Code Draft Session (13m) H O C U R M

	1	2	1	1	Cumings, Mrs. John Bradley (Florence Briggs Th...	female	38.0	1	0	PC 17599	71.2833	C85	C
2	3	1	3	Heikkinen, Miss. Laina	female	26.0	0	0	STON/OZ.	3101282	7.9250	NaN	S
3	4	1	1	Futrelle, Mrs. Jacques Heath (Lily May Peel)	female	35.0	1	0	113803	53.1000	C123	S	
4	5	0	3	Allen, Mr. William Henry	male	35.0	0	0	373450	8.0500	NaN	S	

The data has a different row for each passenger.

The next code cell defines and prints the values of three variables:

- total = total number of passengers who boarded the ship
- survived = number of passengers who survived the shipwreck
- minors = number of passengers under 18 years of age

Run the code cell without changes. (Don't worry about the details of how these variables are calculated for now. You can learn more about how to calculate these values in the [Pandas course](#).)

```
[8]: # Number of total passengers
total = len(titanic_data)
print(total)

# Number of passengers who survived
survived = (titanic_data.Survived == 1).sum()
print(survived)

# Number of passengers under 18
minors = (titanic_data.Age < 18).sum()
print(minors)
```

891  
342  
113

So,

- total = 891 (there were 891 passengers on board the Titanic),
- survived = 342 (342 passengers survived), and
- minors = 113 (113 passengers were under the age of 18).

In the code cell below, replace the underlines ( \_\_\_\_\_ ) with code to calculate the values for two more variables:

- survived\_fraction should be set to the fraction of passengers who survived the Titanic disaster.
- minors\_fraction should be the fraction of passengers who were minors (under the age of 18).

For each variable, your answer should be a number between 0 and 1.

If you need a hint or want to view the solution, you can skip to the next code cell and uncomment the appropriate lines of code (`q5_hint()` and `q5.solution()`).

```
# TODO: Fill in the value of the survived_fraction variable
survived_fraction = survived / total

# Print the value of the variable
print(survived_fraction)

# TODO: Fill in the value of the minors_fraction variable
minors_fraction = minors / total

# Print the value of the variable
print(minors_fraction)

# DO NOT REMOVE: Check your answer
q5.check()
```

print('Setup complete.')

Setup complete.

### Question 1

In the [House Prices - Advanced Regression Techniques competition](#), you need to use information like the number of bedrooms and bathrooms to predict the price of a house. Inspired by this competition, you'll write your own function to do this.

In the next code cell, create a function `get_expected_cost()` that has two arguments:

- `beds` - number of bedrooms
- `baths` - number of bathrooms

It should return the expected cost of a house with that number of bedrooms and bathrooms. Assume that:

- the expected cost for a house with 0 bedrooms and 0 bathrooms is `80000`.
- each bedroom adds `30000` to the expected cost
- each bathroom adds `10000` to the expected cost.

For instance,

- a house with 1 bedroom and 1 bathroom has an expected cost of `120000`, and
- a house with 2 bedrooms and 1 bathroom has an expected cost of `150000`.

+ Code + Markdown

```
[2]: # TODO: Complete the function
def get_expected_cost(beds, baths):
    value = 80000 + beds * 30000 + baths * 10000
    return value

# Check your answer
q1.check()
```

Correct

```
[ ]: # Uncomment to see a hint
#q1.hint()

# Uncomment to view the solution
#q1.solution()
```

### Question 2

You are thinking about buying a home and want to get an idea of how much you will spend, based on the number of bedrooms and bathrooms. You are trying to decide between four different options:

- Option 1: house with two bedrooms and three bathrooms
- Option 2: house with three bedrooms and two bathrooms
- Option 3: house with three bedrooms and three bathrooms
- Option 4: house with three bedrooms and four bathrooms

Use the `get_expected_cost()` function you defined in question 1 to set `option_1`, `option_2`, `option_3`, and `option_4` to the expected cost of each option.

```
[3]: # TODO: Use the get_expected_cost function to fill in each value
option_one = get_expected_cost(2,3)
option_two = get_expected_cost(3,2)
option_three = get_expected_cost(3,3)
option_four = get_expected_cost(3,4)

print(option_one)
print(option_two)
print(option_three)
print(option_four)

# Check your answer
q2.check()
```

170000  
190000  
200000  
210000

Correct

Code Draft Session (18m) H D C P R M

### Question 3

You're a home decorator, and you'd like to use Python to streamline some of your work. Specifically, you're creating a tool that you intend to use to calculate the cost of painting a room.

As a first step, define a function `get_cost()` that takes as input:

- `sqft_walls` = total square feet of walls to be painted
- `sqft_ceiling` = square feet of ceiling to be painted
- `sqft_per_gallon` = number of square feet that you can cover with one gallon of paint
- `cost_per_gallon` = cost (in dollars) of one gallon of paint

It should return the cost (in dollars) of putting one coat of paint on all walls and the ceiling. Assume you can buy the exact amount of paint that you need, so you can buy partial gallons (e.g., if you need 7.523 gallons, you can buy that exact amount, instead of needing to buy 8 gallons and waste some paint). Do not round your answer.

```
# TODO: Finish defining the function
def get_cost(sqft_walls, sqft_ceiling, sqft_per_gallon, cost_per_gallon):
    cost = ((sqft_walls + sqft_ceiling)/sqft_per_gallon) * cost_per_gallon
    return cost

# Check your answer
q3.check()
```

Correct

[7]:

```
# Uncomment to see a hint
q3.hint()

# Uncomment to view the solution
#q3.solution()
```

Hint: Begin by calculating the total number of square feet that need to be painted. Then, based on that, figure out how many gallons you need. Then, once you know how many gallons you need, you can calculate the total cost of the project.

### Question 4

Use the `get_cost()` function you defined in Question 3 to calculate the cost of applying one coat of paint to a room with:

- 432 square feet of walls, and
- 144 square feet of ceiling.

Assume that one gallon of paint covers 400 square feet and costs \$15. As in Question 3, assume you can buy partial gallons of paint. Do not round your answer.

```
[11]:
```

```
# TODO: Set the project_cost variable to the cost of the project
project_cost = get_cost(432, 144, 400, 15)

# Check your answer
q4.check()
```

Correct

[ ]:

```
# Uncomment to see a hint
#q4.hint()

# Uncomment to view the solution
#q4.solution()
```

### Question 5

Now say you can no longer buy fractions of a gallon. (For instance, if you need 4.3 gallons to do a project, then you have to buy 5 gallons of paint.)

With this new scenario, you will create a new function `get_actual_cost` that uses the same inputs and calculates the cost of your project.

One function that you'll need to use to do this is `math.ceil()`. We demonstrate usage of this function in the code cell below. It takes as a number as input and rounds the number up to the nearest integer.

Exercise: Functions Failed to save draft.

File Edit View Run Add-ons Help

+ X Run All Code Draft Session (18m) H O C P R A

One function that you'll need to use to do this is `math.ceil()`. We demonstrate usage of this function in the code cell below. It takes as a number as input and rounds the number up to the nearest integer.

Run the next code cell to test this function for yourself. Feel free to change the value of `test_value` and make sure `math.ceil()` returns the number you expect.

```
[15]: test_value = 5.3
rounded_value = math.ceil(test_value)
print(rounded_value)
```

6

Use the next code cell to define the function `get_actual_cost()`. You'll need to use the `math.ceil()` function to do this.

When answering this question, note that it's completely valid to define a function that makes use of another function. For instance, we can define a function `round_up_and_divide_by_three` that makes use of the `math.ceil` function:

```
def round_up_and_divide_by_three(num):
    new_value = math.ceil(num)
    final_value = new_value / 3
    return final_value
```

```
[20]: def get_actual_cost(sqft_walls, sqft_ceiling, sqft_per_gallon, cost_per_gallon):
    cost = (math.ceil((sqft_walls + sqft_ceiling)/sqft_per_gallon)) * cost_per_gallon
    return cost

# Check your answer
q5.check()
```

Correct

```
[ ]: # Uncomment to see a hint
#q5.hint()

# Uncomment to view the solution
#q5.solution()
```

Once your function is verified as correct, run the next code cell to calculate the updated cost of your project.

```
[21]: get_actual_cost(432, 144, 400, 15)
```

30

Say you're working with a slightly larger room. Run the next code cell to calculate the cost of the project.

```
[22]: get_actual_cost(594, 288, 400, 15)
```

45

+ Code + Markdown

+ X | k Functions | Kaggle | Exercise: Functions | Data Types | Kaggle | Exercise: Data Types | Kaggle | +

This notebook is an exercise in the [Intro to Programming](#) course. You can reference the tutorial at [this link](#).

In the tutorial, you learned about four different data types: floats, integers, strings, and booleans. In this exercise, you'll experiment with them.

## Set up the notebook

Run the next code cell without changes to set up the notebook.

```
[8]: # Set up the exercise
from learntools.core import binder
binder.bind(globals())
from learntools.intro_to_programming.ex3 import *
print('Setup complete.')
```

Setup complete.

## Question 1

You have seen how to convert a float to an integer with the `int` function. Try this out yourself by running the code cell below.

```
[9]: # Define a float
y = 1.
print(y)
print(type(y))

# Convert float to integer with the int function
z = int(y)
print(z)
print(type(z))
```

1.0  
<class 'float'>  
1  
<class 'int'>

In this case, the float you are using has no numbers after the decimal.

- But what happens when you try to convert a float with a fractional part to an integer?
- How does the outcome of the `int` function change for positive and negative numbers?

Use the next code cell to investigate and answer these questions. Feel free to add or remove any lines of code -- it is your workspace!

```
[10]: # Uncomment and run this code to get started!
print(int(1.2321))
print(int(1.747))
print(int(-3.94535))
print(int(-2.19774))
```

1  
1  
-3  
-2

Once you have an answer, run the code cell below to see the solution. Viewing the solution will give you credit for answering the problem.

```
[ ]: # Check your answer (Run this code cell to receive credit!)
q1.check()
```

## Question 2

In the tutorial, you learned about booleans (which can take a value of `True` or `False`), in addition to integers, floats, and strings. For this question, your goal is to determine what happens when you multiply a boolean by any of these data types. Specifically,

+ X D C R

## Question 2

In the tutorial, you learned about booleans (which can take a value of `True` or `False`), in addition to integers, floats, and strings. For this question, your goal is to determine what happens when you multiply a boolean by any of these data types. Specifically,

- What happens when you multiply an integer or float by `True`? What happens when you multiply them by `False`? How does the answer change if the numbers are positive or negative?
- What happens when you multiply a string by `True`? By `False`?

Use the next code cell for your investigation.

```
[11]: # Uncomment and run this code to get started!
print(3 * True)
print(-3.1 * True)
print(type("abc" * False))
print(len("abc" * False))

3
-3.1
<class 'str'>
0
```

Once you have an answer, run the code cell below to see the solution. Viewing the solution will give you credit for answering the problem.

```
[12]: # Check your answer (Run this code cell to receive credit!)
q2.check()
```

Correct:

When you multiply an integer or float by a boolean with value `True`, it just returns that same integer or float (and is equivalent to multiplying by 1). If you multiply an integer or float by a boolean with value `False`, it always returns 0. This is true for both positive and negative numbers. If you multiply a string by a boolean with value `True`, it just returns that same string. And if you multiply a string by a boolean with value `False`, it returns an empty string (or a string with length zero).

## Question 3

In this question, you will build off your work from the previous exercise to write a function that estimates the value of a house.

Use the next code cell to create a function `get_expected_cost` that takes as input three variables:

- `beds` - number of bedrooms (data type float)
- `baths` - number of bathrooms (data type float)
- `has_basement` - whether or not the house has a basement (data type boolean)

It should return the expected cost of a house with those characteristics. Assume that:

- the expected cost for a house with 0 bedrooms and 0 bathrooms, and no basement is 80000.
- each bedroom adds 30000 to the expected cost.
- each bathroom adds 10000 to the expected cost, and
- a basement adds 40000 to the expected cost.

For instance,

- a house with 1 bedroom, 1 bathroom, and no basement has an expected cost of  $80000 + 30000 + 10000 = 120000$ . This value will be calculated with `get_expected_cost(1, 1, False)`.
- a house with 2 bedrooms, 1 bathroom, and a basement has an expected cost of  $80000 + 2*30000 + 10000 + 40000 = 190000$ . This value will be calculated with `get_expected_cost(2, 1, True)`.

Remember you can always get a hint by uncommenting `q3.hint()` in the code cell following the next!

```
[13]: # TODO: Complete the function
def get_expected_cost(beds, baths, has_basement):
    value = 80000 + beds * 30000 + baths * 10000 + has_basement * 40000
    return value

# Check your answer
q3.check()
```

Correct

**Notebook**

**Data**

Once you have an answer, run the code cell below to see the solution. Viewing the solution will give you credit for answering the problem.

[15]:

```
# Check your answer (Run this code cell to receive credit!)
q4.check()
```

Correct:

When you add booleans, adding `False` is equivalent to adding 0, and adding `True` is equivalent to adding 1.

## Question 5

You own an online shop where you sell rings with custom engravings. You offer both gold plated and solid gold rings.

- Gold plated rings have a base cost of \$50, and you charge \$7 per engraved unit.
- Solid gold rings have a base cost of \$100, and you charge \$10 per engraved unit.
- Spaces and punctuation are counted as engraved units.

Write a function `cost_of_project()` that takes two arguments:

- `engraving` - a Python string with the text of the engraving
- `solid_gold` - a Boolean that indicates whether the ring is solid gold

It should return the cost of the project. This question should be fairly challenging, and you may need a hint.

[26]:

```
def cost_of_project(engraving, solid_gold):
    cost = solid_gold * (100 + len(engraving) * 10) + (not solid_gold) * (50 + len(engraving) * 7)
    return cost

# Check your answer
q5.check()
```

Correct

# Uncomment to see a hint  
#q5.hint()  
  
# Uncomment to view the solution  
#q5.solution()

+ Code + Markdown

Run the next code cell to calculate the cost of engraving `Charlie+Denver` on a solid gold ring.

[27]:

```
project_one = cost_of_project("Charlie+Denver", True)
print(project_one)
```

240

Use the next code cell to calculate the cost of engraving `08/10/2000` on a gold plated ring.

[28]:

```
project_two = cost_of_project("08/10/2000", False)
print(project_two)
```

## Exercise: Conditions and Conditional Statements

This notebook is an exercise in the [Intro to Programming](#) course. You can reference the tutorial at [this link](#).

In the tutorial, you learned about conditions and conditional statements. In this exercise, you will use what you learned to answer several questions.

### Set up the notebook

Run the next code cell without changes to set up the notebook.

```
[1]: from learntools.core import binder
binder.bind(globals())
from learntools.intro_to_programming.ex4 import *
print('Setup complete.')
```

Setup complete.

### Question 1

You work at a college admissions office. When inspecting a dataset of college applicants, you notice that some students have represented their grades with letters ("A", "B", "C", "D", "F"), whereas others have represented their grades with a number between 0 and 100.

You realize that for consistency, all of the grades should be formatted in the same way, and you decide to format them all as letters. For the conversion, you decide to assign:

- "A" - any grade 90-100, inclusive
- "B" - any grade 80-89, inclusive
- "C" - any grade 70-79, inclusive
- "D" - any grade 60-69, inclusive
- "F" - any grade <60

Write a function `get_grade()` that takes as input:

- `score` - an integer 0-100 corresponding to a numerical grade

It should return a Python string with the letter grade that it corresponds to. For instance,

- A score of 85 corresponds to a B grade. In other words, `get_grade(85)` should return "B".
- A score of 49 corresponds to an F grade. In other words, `get_grade(49)` should return "F".

Make sure that when supplying the grade that is returned by the function, it is enclosed in quotes. (For instance, if you want to return "A", you should write `return "A"` and not `return A`.)

```
[9]: # TODO: Edit the function to return the correct grade for different scores
def get_grade(score):
    if score >= 90:
        grade = "A"
    elif score >= 80:
        grade = "B"
    elif score >= 70:
        grade = "C"
    elif score >= 60:
        grade = "D"
    else:
        grade = "F"
    return grade

# Check your answer
q1.check()
```

Correct

```
[8]: # Uncomment to see a hint
#q1.hint()

# Uncomment to see the solution
#q1.solution()
```

### Question 2

## Question 2

In the exercise for the previous lesson, you wrote a function `cost_of_project()` that estimated the price of rings for an online shop that sells rings with custom engravings. This function did not use conditional statements. In this exercise, you will rewrite the function to use conditional statements. Recall that the online shop has the following price structure:

- Gold plated rings have a base cost of \$50, and you charge \$7 per engraved unit.
- Solid gold rings have a base cost of \$100, and you charge \$10 per engraved unit.
- Spaces and punctuation are counted as engraved units.

Your function `cost_of_project()` takes two arguments:

- `engraving` - a Python string with the text of the engraving
- `solid_gold` - a Boolean that indicates whether the ring is solid gold

It should return the cost of the project.

The function has been partially completed for you, and you need to fill in the blanks to complete the function.

```
[10]: def cost_of_project(engraving, solid_gold):
    if solid_gold == True:
        cost = 100 + len(engraving) * 10
    else:
        cost = 50 + len(engraving) * 7
    return cost

# Check your answer
q2.check()
```

Correct

```
[ ]: # Uncomment to see a hint
#q2.hint()

# Uncomment to see the solution
#q2.solution()
```

## Question 3

You are a programmer at a water agency. Recently, you have been tasked to write a function `get_water_bill()` that takes as input:

- `num_gallons` = the number of gallons of water that a customer used that month. (This will always be an integer with no decimal part.)

It should output the water bill.

The water agency uses this pricing structure:

Tier	Amount in gallons	Price per 1000 gallons
Tier 1	0 - 8,000	\$5
Tier 2	8,001 - 22,000	\$6
Tier 3	22,001 - 30,000	\$7
Tier 4	30,001+	\$10

For example:

- Someone who uses 10,000 gallons of water in a month is placed in Tier 2, and needs to pay a water bill of  $\$6 \times 10 = \$60$ . In other words, `get_water_bill(10000)` should return `60.0`.
- Someone who uses 25,000 gallons of water in a month is placed in Tier 3, and needs to pay a water bill of  $\$7 \times 25 = \$175$ . In other words, `get_water_bill(25000)` should return `175.0`.

**Do not round your answer.** So, your answer might return fractions of a penny.

```
[11]: # TODO: Edit the function to return the correct bill for different
# values of num_gallons
def get_water_bill(num_gallons):
    if num_gallons > 30000:
        bill = (num_gallons / 1000) * 10
    elif num_gallons > 22000:
        bill = (num_gallons / 1000) * 7
    elif num_gallons > 8000:
        bill = (num_gallons / 1000) * 6
    else:
        bill = (num_gallons / 1000) * 5
    return bill

# Check your answer
```

Question 4

You work for a company that provides data services. For \$100/month, your company provides 15 gigabytes (GB) of data. Then, any additional data is billed at \$0.10/MB (or \$100/GB, since 1,000 MB are in 1 GB).

Use the next code cell to write a function `get_phone_bill()` that takes as input:

- `gb` = number of GB that the customer used in a month

It should return the customer's total phone bill.

For instance:

- A customer who uses 10 GB of data in one month is billed only \$100, since the usage stayed under 15 GB. In other words, `get_phone_bill(10)` should return `100`.
- A customer who uses 15.1 GB (or 15 GB + 100 MB) of data in one month has gone over by .1 GB, so they must pay \$100 (cost of plan), plus  $\$0.10 \times 100 = \$10$ , for a total bill of \$110. In other words, `get_phone_bill(15.1)` should return `110`.

Do not round your answer.

+ Code + Markdown

```
[12]: # TODO: Edit the function to return the correct bill for different
# values of GB
def get_phone_bill(gb):
    if gb > 15:
        bill = 100 + (gb - 15) * 100
    else:
        bill = 100
    return bill

## Question 5

In Mexico, foods and beverages that are high in saturated fat, trans fat, sugar, sodium, and/or calories appear with warning labels that are designed to help consumers make healthy food choices.

For instance, the box of cookies in the image below appears with two labels (in the upper right corner):

- EXCESO CALORÍAS (in English, EXCESS CALORIES)
- EXCESO AZÚCARES (in English, EXCESS SUGAR)

In this question, you'll work with a function `get_labels()` that takes the nutritional details about a food item and prints the needed warning labels. This function takes several inputs:

- `food_type` = one of "solid" or "liquid"
- `serving_size` = size of one serving (if solid, in grams; if liquid, in milliliters)
- `calories_per_serving` = calories in one serving
- `saturated_fat_g` = grams of saturated fat in one serving
- `trans_fat_g` = grams of trans fat in one serving
- `sodium_mg` = mg of sodium in one serving
- `sugars_g` = grams of sugar in one serving

Note that some of the code here should feel unfamiliar to you, since we have not shared the details of how some of the functions like `excess_sugar()` or `excess_saturated_fat()` work. But at a high level, these are functions that return a value of `True` if the food is deemed to have an excess of sugar or saturated fat, respectively. These functions are used within the `get_labels()` function, and whenever there is an excess (of sugar or saturated fat, but also of trans fat, sodium, or calories), it prints the corresponding label.

```
[17]: # import functions needed to make get_labels work
from learntools.intro_to_programming.ex4q5 import excess_sugar, excess_saturated_fat, exc
```

```
[18]: def get_labels(food_type, serving_size, calories_per_serving, saturated_fat_g, trans_fat_g):
    # Print messages based on findings
    if excess_sugar(sugars_g, calories_per_serving) == True:
        print("EXCESO AZÚCARES / EXCESS SUGAR")
    if excess_saturated_fat(saturated_fat_g, calories_per_serving) == True:
        print("EXCESO GRASAS SATURADAS / EXCESS SATURATED FAT")
    if excess_trans_fat(trans_fat_g, calories_per_serving) == True:
        print("EXCESO GRASAS TRANS / EXCESS TRANS FAT")
    if excess_sodium(calories_per_serving, sodium_mg) == True:
        print("EXCESO SODIO / EXCESS SODIUM")
    if excess_calories(food_type, calories_per_serving, serving_size) == True:
        print("EXCESO CALORÍAS / EXCESS CALORIES")
```

The next code cell demonstrates how to use `get_labels()` to get the warning labels that the food item should contain. We begin with `bologna`. Here is an image with all of the nutritional information. Note that for this food,

- `food_type` = "solid" (because bologna is a solid and not a liquid)
- `serving_size` = 32 (the serving size is 32 grams)
- `calories_per_serving` = 110 (there are 110 calories per serving)
- `saturated_fat_g` = 2.5 (there are 2.5 grams of saturated fat per serving)
- `trans_fat_g` = 0 (there are 0 grams of trans fat per serving)
- `sodium_mg` = 400 (there are 400 mg of sodium per serving)
- `sugars_g` = 1 (the nutrition facts say <1g, but we will round it up to 1 gram per serving to be safe)

By supplying all of these values to the function, we can print the warning labels.

```
[19]: # bologna https://world.openfoodfacts.org/product/4099100179378/bologna
get_labels("solid", 32, 110, 2.5, 0, 400, 1)
```

EXCESO GRASAS SATURADAS / EXCESS SATURATED FAT  
EXCESO SODIO / EXCESS SODIUM

Screenshot of a Jupyter Notebook exercise titled "Exercise: Conditions and Conditional Statements". The exercise involves filling in nutritional values for food items. Two code cells are shown:

```
[26]: # zucaritas cereal https://world.openfoodfacts.org/product/7501008023624/zucaritas-kellogg
# TODO: Uncomment the line below, fill in the values, and run the function
get_labels("solid", 40, 150, 0, 0, 150, 16)

EXCESO AZÚCARES / EXCESS SUGAR
EXCESO SODIO / EXCESS SODIUM
EXCESO CALORÍAS / EXCESS CALORIES
```

Next, try these mozzarella sticks. Here is an image with all of the nutritional information.

```
[28]: # mozzarella sticks https://world-es.openfoodfacts.org/product/0062325540104/mozzarella
# TODO: Uncomment the line below, fill in the values, and run the function
get_labels("solid", 21, 68, 3, 0.2, 208, 0)

EXCESO GRASAS SATURADAS / EXCESS SATURATED FAT
EXCESO GRASAS TRANS / EXCESS TRANS FAT
EXCESO SODIO / EXCESS SODIUM
EXCESO CALORÍAS / EXCESS CALORIES
```

Two browser windows show nutritional facts for "Mozzarella Sticks" and "Zucaritas cereal".

Once you have determined the labels for all of the food items, you're ready to move on to the next lesson!

Keep going

Continue to the next lesson to learn about Python lists.

[kaggle.com/code/vemaiensi/exercise-intro-to-lists/edit](https://kaggle.com/code/vemaiensi/exercise-intro-to-lists/edit)

Exercise: Intro to Lists

This notebook is an exercise in the [Intro to Programming](#) course. You can reference the tutorial at [this link](#).

In the tutorial, you learned how to define and modify Python lists. In this exercise, you will use your new knowledge to solve several problems.

## Set up the notebook

Run the next code cell without changes to set up the notebook.

```
[1]: from learntools.core import binder
binder.bind(globals())
from learntools.intro_to_programming.ex5 import *
print('Setup complete.')
```

Setup complete.

## Question 1

You own a restaurant with five food dishes, organized in the Python list `menu` below. One day, you decide to:

- remove bean soup ('bean soup') from the menu, and
- add roasted beet salad ('roasted beet salad') to the menu.

Implement this change to the list below. While completing this task,

- do not change the line that creates the `menu` list.
- your answer should use `.remove()` and `.append()`.

```
[2]: # Do not change: Initial menu for your restaurant
menu = ['stewed meat with onions', 'bean soup', 'risotto with trout and shrimp',
        'fish soup with cream and onion', 'gyro']

# TODO: remove 'bean soup', and add 'roasted beet salad' to the end of the menu
menu.remove('bean soup')
menu.append("roasted beet salad")

# Do not change: Check your answer
q1.check()
```

Correct

```
[ ]: # Uncomment to see a hint
#q1.hint()

# Uncomment to see the solution
#q1.solution()
```

## Question 2

The list `num_customers` contains the number of customers who came into your restaurant every day over the last month (which lasted thirty days). Fill in values for each of the following:

- `avg_first_seven` - average number of customers who visited in the first seven days
- `avg_last_seven` - average number of customers who visited in the last seven days
- `max_month` - number of customers on the day that got the most customers in the last month
- `min_month` - number of customers on the day that got the least customers in the last month

Answer this question by writing code. For instance, if you have to find the minimum value in a list, use `min()` instead of scanning for the smallest value and directly filling in a number.

```
[8]: # Do not change: Number of customers each day for the last month
num_customers = [137, 147, 135, 128, 170, 174, 165, 146, 126, 159,
                 141, 148, 132, 147, 168, 153, 170, 161, 148, 152,
                 141, 151, 131, 149, 164, 163, 143, 143, 166, 171]

# TODO: Fill in values for the variables below
avg_first_seven = sum(num_customers[:7])/7
avg_last_seven = sum(num_customers[-7:])/7
max_month = max(num_customers)
```

**Great work!**

[8]:

```
# Do not change: Number of customers each day for the last month
num_customers = [137, 147, 135, 128, 170, 174, 165, 146, 126, 159,
                 141, 148, 132, 147, 168, 153, 170, 161, 148, 152,
                 141, 151, 131, 149, 164, 163, 143, 143, 166, 171]

# TODO: Fill in values for the variables below
avg_first_seven = sum(num_customers[:7])/7
avg_last_seven = sum(num_customers[-7:])/7
max_month = max(num_customers)
min_month = min(num_customers)

# Do not change: Check your answer
q2.check()
```

Correct

[9]:

```
# Uncomment to see a hint
#q2.hint()

# Uncomment to see the solution
#q2.solution()
```

### Question 3

In the tutorial, we gave an example of a Python string with information that was better as a list.

[11]:

```
flowers = "pink primrose,hard-leaved pocket orchid,canterbury bells,sweet pea,english marigold,tiger lily,moon orchid,bird of paradise,monkshood,globe thistle"
```

You can actually use Python to quickly turn this string into a list with `.split()`. In the parentheses, we need to provide the character that should be used to mark the end of one list item and the beginning of another, and enclose it in quotation marks. In this case, that character is a comma.

[12]:

```
print(flowers.split(","))
```

```
['pink primrose', 'hard-leaved pocket orchid', 'canterbury bells', 'sweet pea', 'english marigold', 'tiger lily', 'moon orchid', 'bird of paradise', 'monkshood', 'globe thistle']
```

Now it is your turn to try this out! Create two Python lists:

- `letters` should be a Python list where each entry is an uppercase letter of the English alphabet. For instance, the first two entries should be "A" and "B", and the final two entries should be "Y" and "Z". Use the string `alphabet` to create this list.
- `address` should be a Python list where each row in `address` is a different item in the list. Currently, each row in `address` is separated by a comma.

[13]:

```
# DO not change: Define two Python strings
alphabet = "A.B.C.D.E.F.G.H.I.J.K.L.M.N.O.P.Q.R.S.T.U.V.W.X.Y.Z"
address = "Mr. H. Potter,The cupboard under the Stairs,4 Privet Drive,Little Whinging,Surrey"

# TODO: Convert strings into Python lists
letters = alphabet.split('.')
formatted_address = address.split(',')

# Do not change: Check your answer
q3.check()
```

Correct

[ ]:

```
# Uncomment to see a hint
#q3.hint()

# Uncomment to see the solution
#q3.solution()
```

**Great work!**

## Question 4

In the Python course, you'll learn all about **list comprehensions**, which allow you to create a list based on the values in another list. In this question, you'll get a brief preview of how they work.

Say we're working with the list below.

```
[14]: test_ratings = [1, 2, 3, 4, 5]
```

Then we can use this list (`test_ratings`) to create a new list (`test_liked`) where each item has been turned into a boolean, depending on whether or not the item is greater than or equal to four.

```
[15]: test_liked = [i>=4 for i in test_ratings]
print(test_liked)

[False, False, False, True, True]
```

In this question, you'll use this list comprehension to define a function `percentage_liked()` that takes one argument as input:

- `ratings`: list of ratings that people gave to a movie, where each rating is a number between 1-5, inclusive

We say someone liked the movie, if they gave a rating of either 4 or 5. Your function should return the percentage of people who liked the movie.

For instance, if we supply a value of `[1, 2, 3, 4, 5, 4, 5, 1]`, then 50% (4/8) of the people liked the movie, and the function should return `0.5`.

Part of the function has already been completed for you. You need only use `list_liked` to calculate `percentage_liked`.

```
[21]:
def percentage_liked(ratings):
    list_liked = [i>=4 for i in ratings]
    # TODO: Complete the function
    percentage_liked = sum(list_liked[:]) / len(ratings)
    return percentage_liked

# Do not change: should return 0.5
percentage_liked([1, 2, 3, 4, 5, 4, 5, 1])

# Do not change: Check your answer
q4.check()
```

Correct

```
[19]:
# Uncomment to see a hint
q4.hint()

# Uncomment to see the solution
#q4.solution()
```

Hint: Remember that when we add booleans, it returns the total number of entries in the sum that are `True`.

## Question 5

Say you're doing analytics for a website. You need to write a function that returns the percentage growth in the total number of users relative to a specified number of years ago.

Your function `percentage_growth()` should take two arguments as input:

- `num_users` = Python list with the total number of users each year. So `num_users[0]` is the total number of users in the first year, `num_users[1]` is the total number of users in the second year, and so on. The list gives the total number of users in the most recently completed year.
- `yrs_ago` = number of years to go back in time when calculating the growth percentage

For instance, say `num_users = [920344, 1043553, 1204334, 1458996, 1503323, 1593432, 16234, 1843064, 1930992, 2001078]`.

## Question 5

Say you're doing analytics for a website. You need to write a function that returns the percentage growth in the total number of users relative to a specified number of years ago.

Your function `percentage_growth()` should take two arguments as input:

- `num_users` = Python list with the total number of users each year. So `num_users[0]` is the total number of users in the first year, `num_users[1]` is the total number of users in the second year, and so on. The final entry in the list gives the total number of users in the most recently completed year.
- `yrs_ago` = number of years to go back in time when calculating the growth percentage

For instance, say `num_users = [920344, 1043553, 1204334, 1458996, 1503323, 1593432, 1623463, 1843064, 1930992, 2001078]`.

- if `yrs_ago = 1`, we want the function to return a value of about `0.036`. This corresponds to a percentage growth of approximately 3.6%, calculated as  $(2001078 - 1930992)/1930992$ .
- if `yrs_ago = 7`, we would want to return approximately `0.66`. This corresponds to a percentage growth of approximately 66%, calculated as  $(2001078 - 1204334)/1204334$ .

Your coworker sent you a draft of a function, but it doesn't seem to be doing the correct calculation. Can you figure out what has gone wrong and make the needed changes?

```

yrs, yrs_ago):
    num_users[-1] - num_users[len(num_users)-yrs_ago-1])/num_users[len(num_users)-yrs_ago-1]

    calculating some test examples
13553, 1204334, 1458996, 1503323, 1593432, 1623463, 1843064, 1930992, 2001078

    .036
    isers_test, 1))

    .66
    isers_test, 7))

    answer

0.03629533421163837
0.6615639847417742

```

**Correct**

[+ Code](#) [+ Markdown](#)

```

[25]: # Uncomment to see a hint
q5_hint()

# Uncomment to see the solution
q5.solution()

```

**Hint:** It's already correct that you need to subtract two numbers from the list, before dividing by an item in the list. You only need to modify the positions for the items that are pulled from the list.

In order to pull the final entry in the `num_users` list, you would need to use `num_users[len(num_users)-1]`. This corresponds to the number of users in the most recently completed year.

Then, to get the number of users from one year prior, you should use `num_users[len(num_users)-2]`.

To get the number of users from `yrs_ago` years ago, use `num_users[len(num_users)-yrs_ago-1]`.

**Solution:**

```

def percentage_growth(num_users, yrs_ago):
    growth = (num_users[-1] - num_users[len(num_users)-yrs_ago-1])/num_users[len(num_users)-yrs_ago-1]
    return growth

```

## Congratulations!

Congratulations for finishing the Intro to Programming course! You should be proud of your very first steps with learning programming. As next steps, we recommend taking:

- the [Python course](#), and
- the [Intro to Machine Learning course](#).

Have questions or comments? Visit the [course discussion forum](#) to chat with other learners.

**Great work!**

You've finished the course. Return to the course page to get your certificate and see bonus lessons.

# Intro to Programming

Get started with Python, if you have no coding experience.

[View Certificate](#)

100% complete! Congrats!

Courses Discussions

## Lessons

Tutorial Exercise

Preparation for  
Python

### 1 Arithmetic and Variables

Make calculations, and define and modify variables.

Hours to earn certificate  
5 (estimated)

### 2 Functions

Organize your code and avoid redundancy.

### Cost

No cost, like all Kaggle Learn Courses

### 3 Data Types

Explore integers, floats, booleans, and strings.

Instructor  
Alexis Cook

### 4 Conditions and Conditional Statements

Modify how functions run, depending on the input.

### 5 Intro to Lists

Organize your data so you can work with it efficiently.

## ⌚ Bonus Lessons

### Apply what you've learned

These lessons aren't required for your certificate, but bridge the gap between courses and applying your new skills!

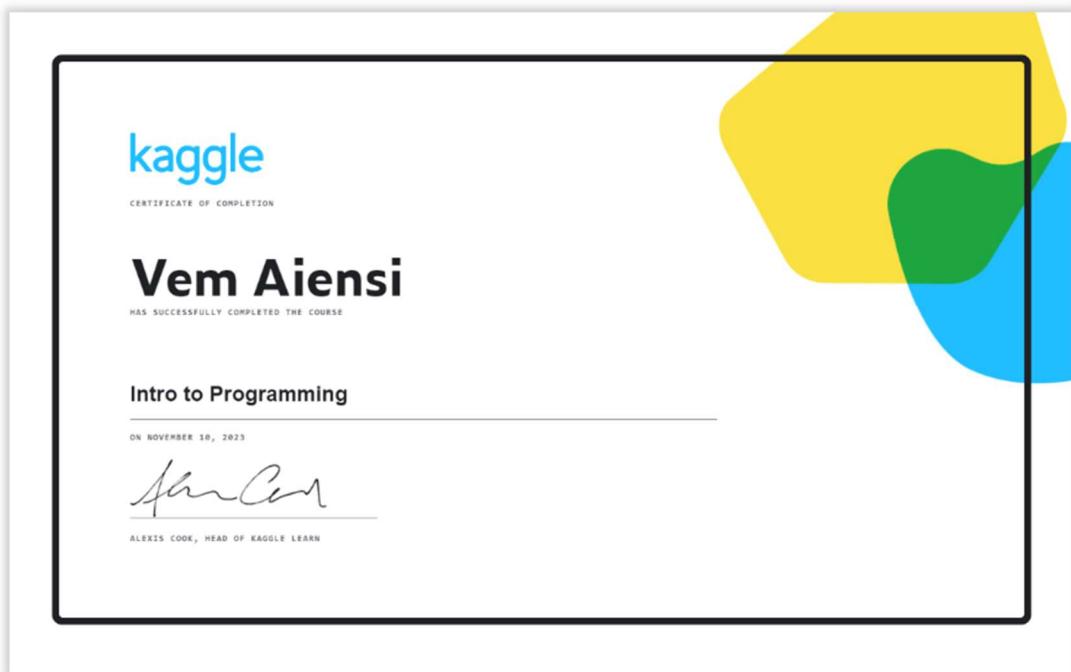

**Titanic Tutorial** 

Make your first submission to a Kaggle competition!

[Return to lesson](#)

## KAGGLE COMPETITION – TITANIC SURVIVAL PREDICTION

The screenshot shows a Kaggle Notebook interface. The main area contains Python code for data analysis and machine learning:

```
print("% of women who survived:", rate_women)
% of women who survived: 0.7420382165605095

[5]: men = train_data.loc[train_data.Sex == 'male'][['Survived']]
rate_men = sum(men)/len(men)
print("% of men who survived:", rate_men)
% of men who survived: 0.18890814558058924

from sklearn.ensemble import RandomForestClassifier
y = train_data['Survived']

features = ['Pclass', 'Sex', 'SibSp', 'Parch']
X = pd.get_dummies(train_data[features])
X_test = pd.get_dummies(test_data[features])

model = RandomForestClassifier(n_estimators=100, max_depth=5, random_state=1)
model.fit(X, y)
predictions = model.predict(X_test)

output = pd.DataFrame({'PassengerId': test_data.PassengerId, 'Survived': predictions})
output.to_csv('submission.csv', index=False)
```

The notebook sidebar shows a list of saved versions of the script. The current version is labeled "Saved!".

On the right, the "Notebook" panel displays the following information:

- Data**: titanic (60KB / 19.5GB)
- Input**: titanic
- Output**: /kaggle/working
- Models**: No models added
- Submit to competition**
- Notebook options**

The screenshot shows a Kaggle competition page for "Titanic Survival Predictions". The left sidebar navigation includes "kaggle", "Create", "Home", "Competitions", "Datasets", "Models", "Code", "Discussions", "Learn", and "More".

The main content area displays the competition details:

### Titanic Survival Predictions

Python - Titanic - Machine Learning from Disaster

Competition Notebook: [Titantic - Machine Learning from Disaster](#)

Run: 12.9s      Public Score: 0.77511      Best Score: 0.77511 V1

Version 1 of 1

The notebook code section shows the following Python code:

```
# This Python 3 environment comes with many helpful analytics libraries installed
# It is defined by the kaggle/python Docker image: https://github.com/kaggle/docker-python
# For example, here's several helpful packages to load

import numpy as np # linear algebra
import pandas as pd # data processing, CSV file I/O (e.g. pd.read_csv)

# Input data files are available in the read-only "../input/" directory
# For example, running this (by clicking run or pressing Shift+Enter) will list all files under the input directory

import os
for dirname, _, filenames in os.walk('/kaggle/input'):
    for filename in filenames:
        print(os.path.join(dirname, filename))

# You can write up to 20GB to the current directory (/kaggle/working/) that gets preserved as output when you create a version using "Save" below.
```

At the bottom, a note states: "Kaggle uses cookies from Google to deliver and enhance the quality of its services and to analyze traffic." with "Learn more." and "Ok, Got it." buttons.

The screenshot shows a Kaggle notebook interface. The left sidebar contains navigation links like Home, Competitions, Datasets, Models, Code, Discussions, Learn, and More. Under 'Your Work', there are entries for 'Titanic - Machine Lear...', 'Titanic Survival Predict...', 'Titanic competition w/ ...', 'Titanic Tutorial', and 'Blender's Device Ben...'. The main area displays Python code and its output.

```

# This Python 3 environment comes with many helpful analytics libraries installed

The screenshot shows the Kaggle interface for the 'Titanic Survival Predictions' competition. On the left, there's a sidebar with navigation links like Home, Competitions, Datasets, Models, Code, Discussions, Learn, and More. Under 'Your Work', several projects are listed, including 'Titanic Survival Predictions'. The main area displays the competition details: 'Titanic - Machine Learning from Disaster' with a note about Python 3 environment setup. Below this is a code editor window showing a snippet of Python code for data processing. To the right, a 'Submit to Competition' dialog box is open, prompting for a notebook selection ('Titanic Survival Predictions'), notebook version ('Version 1'), output file ('submission.csv'), and a description. At the bottom right of the dialog are 'Cancel' and 'Submit' buttons.

This screenshot shows the same competition page after a submission has been made. The 'Submissions' section now lists a single entry: 'Titanic Survival Predictions - Version 1' with a green checkmark icon, indicating it is complete. To the right of the submission is its public score, '0.7751'. The rest of the page remains consistent with the previous screenshot, showing the competition title, description, and navigation links.
